**SYSTEM AND APPARATUS FOR CONNECTING A WIRELESS
DEVICE TO A REMOTE LOCATION ON A NETWORK**

TECHNICAL FIELD OF THE INVENTION

This invention is related to an apparatus for computer control. In one aspect, it relates to an apparatus for automatically connecting a nearby wireless device to a remote location on a computer network.

5 CROSS REFERENCE TO RELATED APPLICATION

This application is a Continuation-in-Part of pending U.S. Patent Application Serial No. 09/378,221 (Atty. Dkt. No. PHL Y-24,669) entitled "METHOD AND APPARATUS FOR ACCESSING A REMOTE LOCATION BY SCANNING AN OPTICAL CODE" filed on August 19, 1999, which is a Continuation-in-Part of the following two U.S. Patent Applications: Pending U.S. Patent Application Serial No. 10 09/151,471 (Atty. Dkt. No. PHL Y-24,397) entitled "METHOD FOR INTERFACING SCANNED PRODUCT INFORMATION WITH A SOURCE FOR THE PRODUCT OVER A GLOBAL NETWORK" filed on September 11, 1998, and U.S. Patent

Application Serial No. 09/151,530 (Atty. Dkt. No. PHL Y-24,398) entitled "METHOD FOR CONTROLLING A COMPUTER WITH AN AUDIO SIGNAL", also filed on September 11, 1998, and issued as U.S. Patent No. 6,098,106 on August 1, 2000. This application is related to pending U.S. Patent Application Serial No. _____

- 5 (Atty. Dkt. No. PHL Y-25,506) entitled "METHOD FOR CONNECTING A WIRELESS DEVICE TO A REMOTE LOCATION ON A NETWORK" filed of even date herewith.

RECEIVED
U.S. PATENT & TRADEMARK OFFICE
SEP 11 2000

BACKGROUND OF THE INVENTION

Global communication networks such as the Internet provide businesses with a new infrastructure for reaching millions of potential customers. So-called "web pages" have become a major vehicle for providing information content (e.g., advertising) to users, and a convenient method for distributing information the users from remote locations on the network.

The emergence of e-commerce over the Internet, and the resulting scramble to capture the attention of users now demands more effective ways for vendors to direct their advertising to potential customers. Such efforts are complicated by the development of so-called wireless devices, e.g., mobile computers and other digital computing devices which are connected to the Internet by means of a radio frequency interface. These wireless devices are frequently employed while the user is actually moving, e.g., walking or traveling in an automobile, train, airplane, etc. Thus, new methods and apparatus are needed to facilitate connection of wireless devices to desired locations on the Internet.

It is known to connect a wireless device to a remote location on a network by manually inputting a network address. However, in many cases the address of a remote location is unknown or unavailable to the user. In other cases, the network address is available (e.g., displayed in advertising), but it is cumbersome or even unsafe (e.g., while driving a car) for the user to enter the desired address using the tiny buttons or stylus often associated with a wireless device. A need therefore exists, for a system for connecting a wireless device to a remote location on a network which does not require the user to manually input a network address.

In many cases, an advertiser desires to provide the user of a wireless device with information or knowledge which is especially relevant to the user's current geographic

SUMMARY OF THE INVENTION

The present invention disclosed and claimed herein comprises, in one aspect thereof, a system for connecting a wireless device to a remote location on a computer network. The wireless device includes a processor and a transmitter/receiver for sending and receiving radio frequency signals to provide two-way digital communication between the processor and the computer network. The system comprises a beacon unit and a beacon signal receiver circuit. The beacon unit is disposed at a location and includes a transmitter which transmits a beacon signal into a target region adjacent to the location. The beacon signal receiver circuit is disposed with the wireless device and adapted to receive the beacon signal when the wireless device is within the target region. The beacon signal receiver circuit is operably connected to the processor of the wireless device. In response to receiving the beacon signal, the beacon signal receiver circuit sends control signals to the processor of the wireless device. In response to the processor receiving the control signals, the wireless device is connected to a remote location on the computer network.

BRIEF DESCRIPTION OF THE DRAWINGS

For a more complete understanding of the present invention and the advantages thereof, reference is now made to the following description taken in conjunction with the accompanying Drawings in which:

PHLY-25,364

DETAILED DESCRIPTION OF THE INVENTION

Referring now to FIGURE 1, there is illustrated a block diagram of a system for controlling a personal computer ("PC") 112 via an audio tone transmitted over a wireless system utilizing a TV. In the embodiment illustrated in FIGURE 1, there is provided a transmission station 101 and a receive station 117 that are connected via a communication link 108. The transmission station 101 is comprised of a television program source 104, which is operable to generate a program in the form of a broadcast signal comprised of video and audio. This is transmitted via conventional techniques along channels in the appropriate frequencies. The program source is input to a mixing device 106, which mixing device is operable to mix in an audio signal. This audio signal is derived from an audio source 100 which comprises a coded audio signal which is then modulated onto a carrier which is combined with the television program source 104. This signal combining can be done at the audio level, or it can even be done at the RF level in the form of a different carrier. However, the preferred method is to merely sum the audio signal from the modulator 102 into the audio channel of the program that is generated by the television program source 104. The output thereof is provided from the mixing device 106 in the form of broadcast signal to an antenna 107, which transmits the information over the communication link 108 to an antenna 109 on the receive side.

On the receive side of the system, a conventional receiver 110, such as a television is provided. This television provides a speaker output which provides the user with an audible signal. This is typically associated with the program. However, the receiver 110 in the disclosed embodiment, also provides an audio output jack, this being the type RCA jack. This jack is utilized to provide an audio output signal on a line 113 which is represented by an audio signal 111. This line 113 provides all of the audio that is received over the communication link 108 to the PC 112 in the audio input port on the PC 112. However, it should be understood that, although a direct connection is illustrated from the

receiver 110 to the PC 112, there actually could be a microphone pickup at the PC 112 which could pick the audio signal up. In the disclosed embodiment, the audio signal generated by the advertiser data input device 100 is audible to the human ear and, therefore, can be heard by the user. Therefore, no special filters are needed to provide this audio to the PC 112.

The PC 112 is operable to run programs thereon which typically are stored in a program file area 116. These programs can be any type of programs such as word processing programs, application programs, etc. In the disclosed embodiment, the program that is utilized in the system is what is referred to as a "browser." The PC 112 runs a browser program to facilitate the access of information on the network, for example, a global communication network known as the "Internet" or the World-Wide-Web ("Web"). The browser is a hypertext-linked application used for accessing information. Hypertext is a term used to describe a particular organization of information within a data processing system, and its presentation to a user. It exploits the computer's ability to link together information from a wide variety of sources to provide the user with the ability to explore a particular topic. The traditional style of presentation used in books employs an organization of the information which is imposed upon it by limitations of the medium, namely fixed sized, sequential paper pages. Hypertext systems, however, use a large number of units of text or other types of data such as image information, graphical information, video information, or sound information, which can vary in size. A collection of such units of information is termed a hypertext document, or where the hypertext documents employ information other than text, hypermedia documents. Multimedia communications may use the Hypertext Transfer Protocol ("HTTP"), and files or formatted data may use the Hypertext Markup Language ("HTML"). This formatting language provides for a mingling of text, graphics, sound, video, and hypertext links by "tagging" a text document using HTML. Data encoded using HTML is often referred to as an "HTML document," an "HTML page," or a "home page." These documents and other

Internet resources may be accessed across the network by means of a network addressing scheme which uses a locator referred to as a Uniform Resource Locator ("URL"), for example, "http://www.digital.com."

5 The Internet is one of the most utilized networks for interconnecting distributed computer systems and allows users of these computer systems to exchange data all over the world. Connected to the Internet are many private networks, for example, corporate or commercial networks. Standard protocols, such as the Transport Control Protocol ("TCP") and the Internet Protocol ("IP") provide a convenient method for communicating across these diverse networks. These protocols dictate how data are formatted and
10 communicated. As a characteristic of the Internet, the protocols are layered in an IP stack. At higher levels of the IP stack, such as the application layer (where HTTP is employed), the user information is more readily visible, while at lower levels, such as the network level (where TCP/IP are used), the data can merely be observed as packets or a stream of rapidly moving digital signals. Superimposed on the Internet is a standard protocol
15 interface for accessing Web resources, such as servers, files, Web pages, mail messages, and the like. One way that Web resources can be accessed is by browsers made by *Netscape®* and *Microsoft Internet Explorer®*.

Referring again now to FIGURE 1, the user can load this program with the appropriate keystrokes such that a browser window will be displayed on a display 118. In
20 one embodiment, the user can run the browser program on the PC 112 such that the browser window is displayed on the display 118. While watching a preferred program, the user can also view display 118. When an audio signal is received by the receiver 110 and the encoded information is contained therein that was input thereto by the advertiser, the PC 112 will then perform a number of operations. The first operation, according to the
25 disclosed embodiment, is to extract the audio information within the received audio signal in the form of digital data, and then transmit this digital data to a defined location on the global

communication network via a modem connection 114. This connection will be described hereinbelow. This information will be relayed to a proprietary location and the instructions sent back to the PC 112 as to the location of the advertiser associated with the code, and the PC 112 will then effect a communication link to that location such that the user can
5 view on the display 118 information that the advertiser, by the fact of putting the tone onto the broadcast channel, desires the viewer to view. This information can be in the form of interactive programs, data files, etc. In one example, when an advertisement appears on the television, the tone can be generated and then additional data displayed on the display 118. Additionally, a streaming video program could be played on the PC received over
10 the network, which streaming video program is actually longer than the advertising segment on the broadcast. Another example would be a sports game that would broadcast the tone in order to allow a user access to information that is not available over the broadcast network, such as additional statistics associated with the sports program, etc.

By utilizing the system described herein with respect to the disclosed embodiment
15 of FIGURE 1, an advertiser is allowed the ability to control a user's PC 112 through the use of tones embedded within a program audio signal. As will described hereinbelow, the disclosed embodiment utilizes particular routing information stored in the PC 112 which allows the encoded information in the received audio signal to route this information to a desired location on the network, and then allow other routing information to be returned to
20 the PC 112 for control thereof to route the PC 112 to the appropriate location associated with that code.

Referring now to FIGURE 2, there is illustrated a computer 204, similar to computer 112, connected to display information on display 118. The computer 204 comprises an internal audio or "sound" card 206 for receiving the transmitted audio signal
25 through receive antenna 109 and receiver 110. The sound card 206 typically contains analog-to-digital circuitry for converting the analog audio signal into a digital signal. The

digital signal may then be more easily manipulated by software programs. The receiver 110 separates the audio signal from the video signal. A special trigger signal located within the transmitted advertiser audio signal triggers proprietary software running on the computer 204 which launches a communication application, in this particular embodiment, the web browser application located on the PC 204. Coded advertiser information contained within the audio signal is then extracted and appended with the address of a proprietary server located on the communication network.

The remote server address is in the form of a URL. This appended data, in addition to other control codes, is inserted directly into the web browser application for automatic routing to the communication network. The web browser running on PC 204, and communicating to the network with an internal modem 208, in this embodiment, transmits the advertiser information to the remote server. The remote server cross-references the advertiser product information to the address of the advertiser server located on the network. The address of the advertiser server is routed back through the PC 204 web browser to the advertiser server. The advertiser product information is returned to PC 204 to be presented to the viewer on display 118. In this particular embodiment, the particular advertiser product information displayed is contained within the advertiser's web page 212. As mentioned above, the audio signal is audible to the human ear. Therefore the audio signal, as emitted from the TV speakers, may be input to the sound card 206 via a microphone. Furthermore, the audio signal need not be a real-time broadcast, but may be on video tapes, CDS, DVD, or other media which may be displayed at a later date. With the imminent implementation of high definition digital television, the audio signal output from the TV may also be digital. Therefore, direct input into a sound card for A/D purposes may not be necessary, but alternative interfacing techniques to accommodate digital-to-digital signal formats would apply.

Referring now to FIGURE 3, there is illustrated a source PC 302, similar to PCS 204 and 112, connected to a global communication network ("GCN") 306 through an interface 304. In this embodiment, the audio signal 111 is received by PC 302 through its sound card 206. The audio signal 111 comprises a trigger signal which triggers proprietary software into launching a web browser application residing on the PC 302. The audio signal 111 also comprises advertiser product information which is extracted and appended with URL information of an Advertiser Reference Server ("ARS") 308. The ARS 308 is a system disposed on the GCN 306 that is defined as the location to which data in the audio signal 111 is to be routed. As such, data in the audio signal 111 will always be routed to the ARS 308, since a URL is unique on the GCN 306. Connected to the ARS 308 is a database 310 of product codes and associated manufacturer URLs. The database 310 undergoes a continual update process which is transparent to the user. As companies sign-on, i.e., subscribe, to this technology, manufacturer and product information is added to the database 310 without interrupting operation of the source PC 302 with frequent updates. When the advertiser server address URL is obtained from the ARS database 310, it and the request for the particular advertiser product information are automatically routed back through the web browser on PC 302, over to the respective advertiser server for retrieval of the advertiser product information to the PC 302. Additionally, although the disclosed invention discusses a global communication network, the system is also applicable to LANs, WANs, and peer-to-peer network configurations. It should be noted that the disclosed architecture is not limited to a single source PC 302, but may comprise a plurality of source PCS, e.g., PC 300 and PC 303. Moreover, a plurality of ARS 308 systems and advertiser servers 312 may be implemented, e.g., ARS 314, and advertiser server A 316, respectively.

The information transactions, in general, which occur between the networked systems of this embodiment, over the communication network, are the following. The web browser running on source PC 302 transmits a message packet to the ARS 308 over Path

“A.” The ARS 308 decodes the message packet and performs a cross-reference function with product information extracted from the received message packet to obtain the address of an advertiser server 312. A new message packet is assembled comprising the advertiser server 312 address, and sent back to the source PC 302 over Path “B.” A
5 “handoff” operation is performed whereby the source PC 302 browser simply reroutes the information on to the advertiser server 312 over Path “C,” with the appropriate source and destination address appended. The advertiser server 312 receives and decodes the message packet. The request-for-advertiser-product-information is extracted and the advertiser 312 retrieves the requested information from its database for transmission back
10 to the source PC 302 over Path “D.” The source PC 302 then processes the information, i.e., for display to the viewer. The optional Path “E” is discussed hereinbelow. It should be noted that the disclosed methods are not limited to only browser communication applications, but may accommodate, with sufficient modifications by one skilled in the art, other communication applications used to transmit information over the Internet or
15 communication network.

Referring now to FIGURE 4a, the message packet 400 sent from the source PC 302 to ARS 308 via Path “A” comprises several fields. One field comprises the URL of the ARS 308 which indicates where the message packet is to be sent. Another field comprises the advertiser product code or other information derived from the audio signal
20 111, and any additional overhead information required for a given transaction. The product code provides a link to the address of the advertiser server 312, located in the database 310. Yet another field comprises the network address of the source PC 302. In general, network transmissions are effected in packets of information, each packet providing a destination address, a source address, and data. These packets vary
25 depending upon the network transmission protocol utilized for communication. Although the protocols utilized in the disclosed embodiment are of a conventional protocol suite commonly known as TCP/IP, it should be understood that any protocols providing the

similar basic functions can be used, with the primary requirement that a browser can forward the routing information to the desired URL in response to keystrokes being input to a PC. Within the context of this disclosure, "message packet" shall refer to and comprise the destination URL, product information, and source address, even though more than a single packet must be transmitted to effect such a transmission.

Upon receipt of the message packet 400 from source PC 302, ARS 308 processes the information in accordance with instructions embedded in the overhead information. The ARS 308 specifically will extract the product code information from the received packet 400 and, once extracted, will then decode this product code information. Once decoded, this information is then compared with data contained within the ARS advertiser database 310 to determine if there is a "hit." If there is no "hit" indicating a match, then information is returned to the browser indicating such. If there is a "hit," a packet 402 is assembled which comprises the address of the source PC 302, and information instructing the source PC 302 as to how to access, directly in a "handoff" operation, another location on the network, that of an advertiser server 312. This type of construction is relatively conventional with browsers such as *Netscape®* and *Microsoft Internet Explorer®* and, rather than displaying information from the ARS 308, the source PC 302 can then access the advertiser server 312. The ARS 308 transmits the packet 402 back to source PC 302 over Path "B." Referring now to FIGURE 4b, the message packet 402 comprises the address of the source PC 302, the URL of the advertiser server 312 embedded within instructional code, and the URL of the ARS 308.

Upon receipt of the message packet 402 by the source PC 302, the message packet 402 is disassembled to obtain pertinent routing information for assembly of a new message packet 404. The web browser running on source PC 302 is now directed to obtain, over Path "C," the product information relevant to the particular advertiser server 312 location information embedded in message packet 404. Referring now to FIGURE

4c, the message packet 404 for this transaction comprises the URL of the advertiser server 312, the request-for-product-information data, and the address of the source PC 302.

Upon receipt of the message packet 404 from source PC 302, advertiser server 312 disassembles the message packet 404 to obtain the request-for-product-information data. The advertiser server 312 then retrieves the particular product information from its database, and transmits it over Path "D" back to the source PC 302. Referring now to FIGURE 4d, the message packet 406 for this particular transaction comprises the address of the source PC 302, the requested information, and the URL of the advertiser server 312.

Optionally, the ARS 308 may make a direct request for product information over Path "E" to advertiser server 312. In this mode, the ARS 308 sends information to the advertiser server 312 instructing it to contact the source PC 302. This, however, is unconventional and requires more complex software control. The message packet 408 for this transaction is illustrated in FIGURE 4e, which comprises the URL of the advertiser server 312, the request-for-product-information data, and the address of the source PC 302. Since product information is not being returned to the ARS 308, but directly to the source PC 302, the message packet 408 requires the return address to be that of the source PC 302. The product information is then passed directly to PC 302 over Path "D."

Referring now to FIGURE 5, the method for detecting and obtaining product information is as follows. In decision block 500, a proprietary application running resident on a source computer PC 302 (similar to PC 204) monitors the audio input for a special trigger signal. Upon detection of the trigger signal, data following the trigger signal is decoded for further processing, in function block 502. In function block 504, the data is buffered for further manipulation. In decision block 506, a determination is made as to whether the data can be properly authenticated. If not, program flow continues through the

“N” signal to function block 520 where the data is discarded. In function block 522, the program then signals for a retransmission of the data. The system then waits for the next trigger signal, in decision block 500. If properly authenticated in decision block 506, program flow continues through the “Y” signal path where the data is then used to launch the web browser application, as indicated in function block 508. In function block 510, the web browser receives the URL data, which is then automatically routed through the computer modem 208 to the network interface 304 and ultimately to the network 306. In function block 514, the ARS 308 responds by returning the URL of advertiser server 312 to the PC 302. In function block 516, the web browser running on the source PC 302, receives the advertiser URL information from the ARS 308, and transmits the URL for the product file to the advertiser server 312. In block 518, the advertiser server 312 responds by sending the product information to the source PC 302 for processing.

The user may obtain the benefits of this architecture by simply downloading the proprietary software over the network. Other methods for obtaining the software are well-known; for example, by CD, diskette, or pre-loaded hard drives.

Referring now to FIGURE 6, there is illustrated a flowchart of the process the ARS 308 may undergo when receiving the message packet 400 from the source PC 302. In decision block 600, the ARS 308 checks for the receipt of the message packet 400. If a message packet 400 is not received, program flow moves along the “N” path to continue waiting for the message. If the message packet 400 is received, program flow continues along path “Y” for message processing. Upon receipt of the message packet 400, in function block 602, the ARS 308 decodes the message packet 400. The product code is then extracted independently in function block 604 in preparation for matching the product code with the appropriate advertiser server address located in the database 310. In function block 606, the product code is then used with a lookup table to retrieve the advertiser server 312 URL of the respective product information contained in the audio

signal data. In function block 608, the ARS 308 then assembles message packet 402 for transmission back to the source PC 302. Function block 610 indicates the process of sending the message packet 402 back to the source PC 302 over Path "B."

Referring now to FIGURE 7, there is illustrated a flowchart of the interactive processes between the source PC 302 and the advertiser server 312. In function block 700, the source PC 302 receives the message packet 402 back from the ARS 308 and begins to decode the packet 402. In function block 702, the URL of the advertiser product information is extracted from the message packet 402 and saved for insertion into the message packet 404 to the advertiser server 312. The message packet 404 is then assembled and sent by the source PC 302 over Path "C" to the advertiser server 312, in function block 704. While the source PC 302 waits, in function block 706, the advertiser server 312 receives the message packet 404 from the source PC 302, in function block 708, and disassembles it. The product information location is then extracted from the message packet 404 in function block 710. The particular product information is retrieved from the advertiser server 312 database for transmission back to the source PC 302. In function block 712, the product information is assembled into message packet 406 and then transmitted back to the source PC 302 over Path "D." Returning to the source PC 302 in function block 714, the advertiser product information contained in the message packet 406 received from the advertiser server 312, is then extracted and processed in function block 716.

Referring now to FIGURE 8, after receipt of a trigger signal, a web browser application on a source PC 302 is automatically launched and computer display 800 presents a browser page 802. Proprietary software running on the source PC 302 processes the audio signal data after being digitized through the sound card 206. The software appropriately prepares the data for insertion directly into the web browser by extracting the product information code and appending keystroke data to this information.

First, a URL page 804 is opened in response to a Ctrl-O command added by the proprietary software as the first character string. Opening URL page 804 automatically positions the cursor in a field 806 where additional keystroke data following the Ctrl-O command will be inserted. After URL page 804 is opened, the hypertext protocol
5 preamble http:// is inserted into the field 806. Next, URL information associated with the location of the ARS 308 is inserted into field 806. Following the ARS 308 URL data are the characters /? to allow entry of variables immediately following the /? characters. In this embodiment, the variable following is the product information code received in the audio signal. The product code information also provides the cross-reference information for
10 obtaining the advertiser URL from the ARS database 310. Next, a carriage return is added to send the URL/product data and close the window 804. After the message packet 400 is transmitted to the ARS 308 from the source PC 302, transactions from the ARS308, to the source PC 302, to the advertiser server 312, and back to the source PC 302, occur quickly and are transparent to the viewer. At this point, the next information
15 the viewer sees is the product information which was received from the advertiser server 312.

Referring now to FIGURE 9, there is illustrated a block diagram of a more simplified embodiment. In this embodiment, a video source 902 is provided which is operable to provide an audio output on an audio cable 901 which provides routing
20 information referred to by reference numeral 904. The routing information 904 is basically information contained within the audio signal. This is an encoded or embedded signal. The important aspect of the routing information 904 is that it is automatically output in realtime as a function of the broadcast of the video program received over the video source 902. Therefore, whenever the program is being broadcast in realtime to the user 908, the routing
25 information 904 will be output whenever the producer of the video desires it to be produced. It should be understood that the box 902 representing the video source could be any type of media that will result in the routing information being output. This could be a

cassette player, a DVD player, an audio cassette, a CD ROM or any such media. It is only important that this is a program that the producer develops which the user 908 watches in a continuous or a streaming manner. Embedded within that program, at a desired point selected by the producer, the routing information 904 is output.

5 The audio information is then routed to a PC 906, which is similar to the PC 112 in FIGURE 1. A user 908 is interfaced with the PC to receive information thereof, the PC 906 having associated therewith a display (not shown). The PC 906 is interfaced with a network 910, similar to the network 306 in FIGURE 3. This network 910 has multiple nodes thereon, one of which is the PC 906, and another of which is represented by a
10 network node 912 which represents remote information. The object of the present embodiment is to access remote information for display to the user 908 by the act of transmitting from the video program in block 902 the routing information 904. This routing information 904 is utilized to allow the PC 906 which has a network "browser" running thereon to "fetch" the remote information at the node 912 over the network 910 for display
15 to the user 908. This routing information 904 is in the form of an embedded code within the audio signal, as was described hereinabove.

Referring now to FIGURE 10, there is illustrated a more detailed block diagram of the embodiment of FIGURE 9. In this embodiment, the PC 906 is split up into a couple of nodes, a first PC 1002 and a second PC 1004. The PC 1002 resides at the node
20 associated with the user 908, and the PC 1004 resides at another node. The PC 1004 represents the ARS 308 of FIGURE 3. The PC 1004 has a database 1006 associated therewith, which is basically the advertiser database 310. Therefore, there are three nodes on the network 910 necessary to implement the disclosed embodiment, the PC 1002, the PC 1004 and the remote information node 912. The routing information 904 is utilized by
25 the PC 1002 for routing to the PC 1004 to determine the location of the remote information node 912 on the network 910. This is returned to the PC 1002 and a

connection made directly with the remote information node 912 and the information retrieved therefrom to the user 908. The routing information 904 basically constitutes primary routing information.

5 Referring now to FIGURE 11, there is illustrated a diagrammatic view of how the network packet is formed for sending the primary routing information to the PC 1004. In general, the primary routing information occupies a single field which primary routing information is then assembled into a data packet with the secondary routing information for transfer to the network 910. This is described hereinabove in detail.

10 Referring now to FIGURE 12, there is illustrated an alternate embodiment to that of FIGURE 9. In this embodiment, the video source 902 has associated therewith an optical region 1202, which optical region 1202 has disposed therein an embedded video code. This embedded video code could be relatively complex or as simple as a grid of dark and white regions, each region in the grid able to have a dark color for a logic "1" or a white region for a logic "0." This will allow a digital value to be disposed within the
15 optical region 1202. A sensor 1204 can then be provided for sensing this video code. In the example above, this would merely require an array of optical detectors, one for each region in the grid to determine whether this is a logic "1" or a logic "0" state. One of the sensed video is then output to the PC 906 for processing thereof to determine the information contained therein, which information contained therein constitutes the primary
20 routing information 904. Thereafter, it is processed as described hereinabove with reference to FIGURE 9.

Referring now to FIGURE 13, there is illustrated a block diagram for an embodiment wherein a user's profile can be forwarded to the original subscriber or
25 manufacturer. The PC 906 has associated therewith a profile database 1302, which profile database 1302 is operable to store a profile of the user 908. This profile is created

when the program, after initial installation, requests profile information to be input in order to activate the program. In addition to the profile, there is also a unique ID that is provided to the user 908 in association with the browser program that runs on the PC 906. This is stored in a storage location represented by a block 1304. This ID 1304 is accessible by a remote location as a "cookie" which is information that is stored in the PC 906 in an accessible location, which accessible location is actually accessible by the remote program running on a remote node.

The ARS 308, which basically constitutes the PC 1004 of FIGURE 10, is operable to have associated therewith a profile database 1308, which profile database 1308 is operable to store profiles for all of the users. The profile database 1308 is a combination of the stored in profile database 1302 for all of the PCS 906 that are attachable to the system. This is to be distinguished from information stored in the database 310 of the ARS 308, the advertiser's database, which contains intermediate destination tables. When the routing information in the primary routing information 904 is forwarded to the ARS 308 and extracted from the original data packet, the lookup procedure described hereinabove can then be performed to determine where this information is to be routed. The profile database 1302 is then utilized for each transaction, wherein each transaction in the form of the routing information received from the primary routing information 904 is compared to the destination tables of database 310 to determine what manufacturer is associated therewith.

The associated ID 1304 that is transmitted along with the routing information in primary routing information 904 is then compared with the profile database 1308 to determine if a profile associated therewith is available. This information is stored in a transaction database 1310 such that, at a later time, for each routing code received in the form of the information in primary routing information 904, there will associated therewith the IDs 1304 of each of the PCS 906. The associated profiles in database 1308, which

are stored in association with IDs 1304, can then be assembled and transmitted to a subscriber as referenced by a subscriber node 1312 on the network 910. The ARS 308 can do this in two modes, a realtime mode or a non-realtime mode. In a realtime mode, each time a PC 906 accesses the advertiser database 310, that user's profile information is uploaded to the subscriber node 1312. At the same time, billing information is generated for that subscriber 1312 which is stored in a billing database 1316. Therefore, the ARS 308 has the ability to inform the subscriber 1312 of each transaction, bill for those transactions, and also provide to the subscriber 1312 profile information regarding who is accessing the particular product advertisement having associated therewith the routing information field 904 for a particular routing code as described hereinabove. This information, once assembled, can then be transmitted to the subscriber 1312 and also be reflected in billing information and stored in the billing information database 1316.

Referring now to FIGURE 14, there is illustrated a flowchart depicting the operation for storing the profile for the user. The program is initiated in a block 1402 and then proceeds to a function block 1404, wherein the system will prompt for the profile upon initiation of the system. This initiation is a function that is set to activate whenever the user initially loads the software that he or she is provided. The purpose for this is to create, in addition to the setup information, a user profile. Once the user is prompted for this, then the program will flow to a decision block 1406 to determine whether the user provides basic or detailed information. This is selectable by the user. If selecting basic, the program will flow to a function block 1408 wherein the user will enter basic information such as name and serial number and possibly an address. However, to provide some incentive to the user to enter more information, the original prompt in function block 1404 would have offers for such things as coupons, discounts, etc., if the user will enter additional information. If the user selects this option, the program flows from the decision block 1406 to a function block 1410. In the function block 1410, the user is prompted to enter specific information such as job, income level, general family history, demographic

information and more. There can be any amount of information collected in this particular function block.

Once all of the information is collected, in either the basic mode or the more specific mode, the program will then flow to a function block 1412 where this information is stored locally. The program then flows to a decision block 1414 to then go on-line to the host or the ARS 308. In general, the user is prompted to determine whether he or she wants to send this information to the host at the present time or to send it later. If he or she selects the "later" option, the program will flow to a function block 1415 to prompt the user at a later time to send the information. In the disclosed embodiment, the user will not be able to utilize the software until the profile information is sent to the host. Therefore, the user may have to activate this at a later time in order to connect with the host.

If the user has selected the option to upload the profile information to the host, the program will flow to the function block 1416 to initiate the connect process and then to a decision block 1418 to determine if the connection has been made. If not, the program will flow along a "N" path to a time to decision block 1420 which will timeout to an error block 1422 or back to the input of the connect decision block 1418. The program, once connected, will then flow along a "Y" path from decision block 1418 to a function block 1428 to send the profile information with the ID of the computer or user to the host. The ID is basically, as described hereinabove, a "cookie" in the computer which is accessed by the program when transmitting to the host. The program will then flow to a function block 1430 to activate the program such that it, at later time, can operate without requiring all of the setup information. In general, all of the operation of this flowchart is performed with a "wizard" which steps the user through the setup process. Once complete, the program will flow to a Done block 1432.

Referring now to FIGURE 15, there is illustrated a flowchart depicting the operation of the host when receiving a transaction. The program is initiated at a Start block 1502 and then proceeds to decision block 1504, wherein it is determined whether the system has received a routing request, i.e., the routing information 904 in the form of a tone, etc., embedded in the audio signal, as described hereinabove with respect to

5

FIGURE 9. The program will loop back around to the input of decision block 1504 until the routing request has been received. At this time, the program will flow along the "Y" path to a function block 1506 to receive the primary routing information and the user ID. Essentially, this primary routing information is extracted from the audio tone, in addition to

10

the user ID. The program then flows to a function block 1508 to look up the manufacturer URL that corresponds to the received primary routing information and then return the necessary command information to the originating PC 108 in order to allow that PC 108 to connect to the destination associated with the primary routing information. Thereafter, the program will flow to a function block 1510 to update the transaction database 1310 for the

15

current transaction. In general, the routing information 904 will be stored as a single field with the associated IDs. The profile database 1308, as described hereinabove, has associated therewith detailed profiles of each user on the system that has activated their software in association with their ID. Since the ID was sent in association with the routing information, what is stored in the transaction database 1310 is the routing code, in

20

association with all of the IDs transmitted to the system in association with that particular routing code. Once this transaction database 1310 has been updated, as described hereinabove, the transactions can be transferred back to the subscriber at node 312 with the detailed profile information from the profile database 1308.

The profile information can be transmitted back to the subscriber or manufacturer

25

at the node 312 in realtime or non-realtime. A decision block 1512 is provided for this, which determines if the delivery is realtime. If realtime, the program will flow along a "Y" path to a function block 1514 wherein the information will be immediately forwarded to the

manufacturer or subscriber. The program will then flow to a function block 1516 wherein the billing for that particular manufacturer or subscriber will be updated in the billing database 1316. The program will then flow into an End block 1518. If it was non-realtime, the program moves along the "N" path to a function block 1520 wherein it is set for a later delivery and it is accrued in the transaction database 1310. In any event, the transaction database 1310 will accrue all information associated with a particular routing code.

With a realtime transaction, it is possible for a manufacturer to place an advertisement in a magazine or to place a product on a shelf at a particular time. The manufacturer can thereafter monitor the times when either the advertisements are or the products are purchased. Of course, they must be scanned into a computer which will provide some delay. However, the manufacturer can gain a very current view of how a product is moving. For example, if a cola manufacturer were to provide a promotional advertisement on, for example, television, indicating that a new cola was going to be placed on the shelf and that the first 1000 purchasers, for example, scanning their code into the network would receive some benefit, such as a chance to win a trip to some famous resort in Florida or some other incentive, the manufacturer would have a very good idea as to how well the advertisement was received. Further, the advertiser would know where the receptive markets were. If this advertiser, for example, had placed the television advertisement in ten cities and received overwhelming response from one city, but very poor response from another city, he would then have some inclination to believe that either the one poor-response city was not a good market or that the advertising medium he had chosen was very poor. Since the advertiser can obtain a relatively instant response and also content with that response as to the demographics of the responder, very important information can be obtained in a relatively short time.

It should be noted that the disclosed embodiment is not limited to a single source PC 302, but may encompass a large number of source computers connected over a global communication network. Additionally, the embodiment is not limited to a single ARS 308 or a single advertiser server 312, but may include a plurality of ARS and advertiser systems, indicated by the addition of ARS 314 and advertiser server A 316, respectively. It should also be noted that this embodiment is not limited only to global communication networks, but also may be used with LAN, WAN, and peer-to-peer configurations.

It should also be noted that the disclosed embodiment is not limited to a personal computer, but is also applicable to, for example, a Network Computer ("NetPC"), a scaled-down version of the PC, or any system which accommodates user interaction and interfaces to information resources.

One typical application of the above noted technique is for providing a triggering event during a program, such as a sport event. In a first example, this may be generated by an advertiser. One could imagine that, due to the cost of advertisements in a high profile sports program, there is a desire to utilize this time wisely. If, for example, an advertiser contracted for 15 seconds worth of advertising time, they could insert within their program a tone containing the routing information. This routing information can then be output to the user's PC 302 which will cause the user's PC 302 to, via the network, obtain information from a remote location typically controlled by the advertiser. This could be in the form of an advertisement of a length longer than that contracted for. Further, this could be an interactive type of advertisement. An important aspect to the type of interaction between the actual broadcast program with the embedded routing information and the manufacturer's site is the fact that there is provided information as to the user's PC 302 and a profile of the user themselves. Therefore, an advertiser can actually gain realtime information as to the number of individuals that are watching their particular advertisement

and also information as to the background of those individuals, profile information, etc.
This can be a very valuable asset to an advertiser.

In another example, the producer of the program, whether it be an on-air program,
a program embedded in a video tape, CD-ROM, DVD, or a cassette, can allow the user
5 to automatically access additional information that is not displayed on the screen. For
example, in a sporting event, various statistics can be provided to the user from a remote
location, merely by the viewer watching the program. When these statistics are provided,
the advertiser can be provided with profile information and background information
regarding the user. This can be important when, for example, the user may record a sports
10 program. If the manufacturer sees that this program routing code is being output from
some device at a time later than the actual broadcast itself, this allows the advertisers to
actually see that their program is still being used and also what type of individual is using it.
Alternatively, the broadcaster could determine the same and actually bill the advertiser an
additional sum for a later broadcast. This is all due to the fact that the routing information
15 automatically, through a PC and a network, will provide an indication to the advertiser the
time at which the actual information was broadcast.

The different type of medium that can be utilized with the above embodiment are
such things as advertisements, which are discussed hereinabove, contests, games, news
programs, education, coupon promotional programs, demonstration media (demos), and
20 photographs, all of which can be broadcast on a private site or a public site. This all will
provide the ability to allow realtime interface with the network and the remote location for
obtaining the routed information and also allow for realtime billing and accounting.

Referring now to FIGURE 16, there is illustrated a general block diagram of a
disclosed embodiment. A bar code scanning input device 1600 is provided by a input
25 device distributor to customers and is associated with that distributor via a input device ID

stored therein. The input device 1600 is either sold or freely distributed to customers for use with their personal computing systems. Since more and more products are being sold using bar codes, it can be appreciated that a user having the input device 1600 can scan bar codes of a multitude of products in order to obtain more information. Information
5 about these products can be made immediately available to the user from the manufacturer for presentation by the user's computer 302. Beyond simply displaying information about the product in which the user is interested, the input device distributor may include additional advertising information for display to the user such as information about other promotions or products provided or sold by the input device distributor. Similarly,
10 advertisers may provide catalogs of advertisements or information in newspapers or periodicals where the user simply scans the bar code associated with the advertisement using the input device 1600 to obtain further information. There is provided a paper source 1602 having contained thereon an advertisement 1604 and an associated bar code 1606. (Note that the disclosed concept is not limited to scanning of bar codes 1606 from
15 paper sources 1602, but is also operable to scan a bar code 1606 on the product itself. Also, the input device 1600 can be any type of device that will scan any type of image having information encoded therein.)

After obtaining the input device 1600 from the input device distributor, the user connects the input device 1600 to their PC 302. During a scanning operation, input device
20 1600 reads bar code data 1606 and the input device ID into a "wedge" interface 1608 for conversion into keyboard data, which keyboard data is passed therefrom into the keyboard input port of PC 302. The importance of the input device ID will be discussed in more detail hereinbelow.

The wedge interface 1608 is simply an interface box containing circuitry that
25 accommodates inputs from both the scanning input device 1600 and a computer keyboard 1610. This merely allows the information scanned by the input device 1600 to be input

into the PC 302. In the disclosed embodiment, the wedge interface 1608 will convert any information. The data output from the input device 1600 is passed into the wedge interface 1608 for conversion into keyboard data which is readily recognizable by the PC 302.

Therefore, the input device 1600 is not required to be connected to a separate port on the PC 302. This data is recognized as a sequence of keystrokes. However, the output of the input device 1600 can be input in any manner compatible with the PC 302. When not receiving scanner data, the wedge interface 1608 simply acts as a pass-through device for keyboard data from the keyboard 1610. In any case, the information is ultimately processed by a processor in the PC 302 and can be presented to the user on a display 1612. The wedge interface 1608 is operable to provide a decoding function for the bar code 1606 and conversion thereof to keystroke input data.

In operation, the product code of a product is provided in the form of a bar code 1606. This bar code 1606 is the "link" to a product. The disclosed embodiment is operable to connect that product information contained in the bar code 1606 with a web page of the manufacturer of that product by utilizing the bar code 1606 as the product "identifier." The program operating on the PC 302 provides routing information to the ARS 308 after launching the browser on the PC 302 and connecting to the ARS 308 over the GCN 306, which ARS 308 then performs the necessary steps to cause the browser to connect to the manufacturer web site, while also providing for an accounting step, as will be described in more detail hereinbelow.

The bar code 1606 by itself is incompatible with any kind of network for the purposes of communication therewith. It is primarily provided for a retail-type setting. Therefore, the information contained in the bar code 1606, by itself, does not allow for anything other than identification of a product, assuming that one has a database 1614 containing information as to a correlation between the product and the bar code 1606.

The wedge interface 1608 is operable to decode the bar code 1606 to extract the encoded information therein, and append to that decoded bar code information relating to an ID for the input device 1600. This information is then forwarded to the ARS 308 by the resident program in the PC 302. This is facilitated by intermediate routing information stored in the program indicating to which node on the GCN 306 the scanned bar code information is to be sent, i.e., to the ARS 308. It is important to note that the information in the bar code 1606 must be converted from its optical image to numerical values which are then ultimately input to the keyboard input port of PC 302 and converted into data compatible with communication software residing on the PC 302 (in this case, HTML language for insertion into a browser program). When the scanned information is input to the PC 302, the resident program launches the browser program and then assembles a communication packet comprised of the URL of the ARS 308, the input device ID and the user ID. If another type of communications program were utilized, then it would have to be converted into language compatible with that program. Of course, a user could actually key in the information on the bar code 102 and then append the appropriate intermediate routing information thereafter. As will be described hereinbelow, the intermediate routing information appended thereto is the URL of the ARS 308 disposed on the GCN 306.

As part of the configuration for using the input device 1600, the PC 302 hosts input device software which is operable to interpret data transmitted from the input device 1600, and to create a message packet having the scanned product information and input device ID, routing information, and a user ID which identifies the user location of the input device 1600. The input device software loads at boot-up of the PC 302 and runs in the background. In response to receiving a scanned bar code 1606, the wedge interface 1608 outputs a keystroke code (e.g., ALT-F10) to bring the input device program into the foreground for interaction by the operating system. The input device program then inserts the necessary information into the browser program. The message packet is then transmitted to interface 304 across the global communication network 306 to the ARS

308. The ARS 308 interrogates the message packet and performs a lookup function using the ARS database 310. If a match is found between particular parameters of the message packet, a return message packet is sent back to the PC 302 for processing.

5 The input device program running on PC 302 functions to partition the browser window displayed to the user into several individual areas. This is for the purpose of preparing to present to the user selected information in each of the individual areas (also called "framing"). The selected information comprises the product information which the user requested by scanning the bar code 1606 using the input device 1600, information about the input device distributor which establishes the identity of the company associated with that particular input device 1600, and at least one or more other frames which may be advertisements related to other products that the input device distributor sells. Note that the advertisements displayed by the input device distributor may be related to the product of interest or totally unrelated. For example, if a user scans the bar code 1606 of a soda from Company A, the input device distributor may generate an advertisement of a new soft drink being marketed by Company A, that it sells. On the other hand, the input device distributor may also structure the display of information to the user such that a user requesting product information of a Product X may get the requested information of Product X along with advertisements for a competing item Product Y. Essentially, the input device distributor is free to generate any advertisement to the user in response to the user requesting product information.

10

15

20

The return message packet transmitted from the ARS 308 to the PC 302 is then transmitted back across the GCN 306 to the advertiser server 312. The advertiser server 312 restructures the message packet and appends the particular product information for transmission back to the PC 302. Upon receiving the particular advertiser information from advertiser server 312, the PC 302 then retransmits a message to the input device

25

distributor site 1616 and E-commerce site 1618 to obtain the information that needs to be framed in the browser window displayed to the user.

Therefore, the input device 1600 is associated with the input device distributor by way of a input device ID such that scanning a product bar code 1606 in order to obtain information about that particular product generates one or more responses from one or more remote sites disposed on the GCN 306. Stored in the input device 1600 is the input device ID which establishes its relationship to the input device distributor. Proprietary input device software running on the PC 302 operates to decode scanned bar code information and the input device ID received from the input device 1600 and wedge interface 1608, and also provides a unique user ID for establishing the location of the user of the input device 1600. The input device software also assembles message packets and works in conjunction with the on-board communication software (e.g., a browser) to automatically route the message packets across the GCN 306 such that the one or more remote sites disposed on the GCN 306 return information to be framed for presentation to the user.

Referring now to FIGURE 17, there is illustrated a conversion circuit of the wedge interface. A microcontroller 1700 provides conversion of the data from the input device 1600 and controls interfacing of the keyboard 1610 and input device 1600 with the PC 302. The microcontroller 1700 has contained therein a memory 1702 or it can have external memory. There are provided a plurality of input device interfaces 1704 to the input device 1600, a plurality of PC interfaces 1706 to the PC 302, and plurality of keyboard interfaces 1708 to the keyboard 1610. In general, the input device interfaces 1704 comprise a serial data line, a ground line, and a power line. Similarly, the keyboard interfaces 1708 comprise a serial data line, a ground line, a clock line, and a power line. The PC 302 provides a clock line, a power line, a serial data, and a ground line for input to the microcontroller 1700. The microcontroller 1700 is operable to receive signals from the

keyboard 1610 and transfer the signals to the PC 302 as keyboard signals. Operation with the keyboard 1610 is essentially a “pass-through” procedure. Data output from the keyboard 1610 is already in keyboard format, and therefore requires no conversion by the wedge interface 1608. With respect to the input device 1600, the serial data is not compatible with a keyboard 1610 and, therefore, it must be converted into a keyboard format in order to allow input thereof to the keyboard input of the PC 302.

The microcontroller 1700 performs this function after decoding this bar code information, and conversion of this bar code information into an appropriate stream of data which is comprised of the bar code information and the appended URL. This appended URL will be pre-stored in the memory 1702 and is programmable at the time of manufacture. It is noted that the memory 1702 is illustrated as being contained within the microcontroller 1702 to provide a single chip solution. However, this could be external memory that is accessible by the microcontroller 1702. Therefore, the microcontroller 1700 provides an interface between the input device 1600 and the keyboard 1610 to the PC 302 which allows the input device 1600 to receive coded information and convert it to keyboard strokes or, alternatively, to merely pass-through the keystrokes from the keyboard 1610. Therefore, the user need not install any type of plug-in circuit board into the motherboard of the PC 302 in order to provide an interface to the input device 1600; rather, the user need only utilize the already available keyboard port in order to input the appropriate data into the system.

In this particular disclosed embodiment, the microcontroller 1700 comprises a PIC16C73 microcontroller by *Microchip Technologies*™. The PIC16C73 device is a low cost CMOS 8-bit microcontroller with an integrated analog-to-digital converter. The PIC16C73 device, as illustrated in the disclosed embodiment, has 192 bytes of RAM and 4k x 4 of EPROM memory. The microcontroller 1700 can accommodate asynchronous or synchronous inputs from input devices connected to it. In this disclosed embodiment,

communication to the keyboard 1610 is synchronous while it is asynchronous when communicating with input device 1600.

It should be noted that, although in this particular embodiment bar code information of the bar code 1606 is input into the keyboard input port of the PC 302, disclosed
5 methods may also be advantageously utilized with high speed port architectures such as Universal Serial Bus (“USB”) and IEEE 1394.

Bar codes are structured to be read in either direction. Timing considerations need to be addressed because of the variety of individuals scanning the bar code introduce a wide variety of scan rates. Bar codes use bars of varying widths. The presence of a black
10 bar generates a positive pulse, and the absence of a black bar generates no pulse. Each character of a conventional bar code has associated therewith seven pulses or bars. Depending on the width of the bars, the time between pulses varies. In this disclosed embodiment, the interface circuitry 1608 performs a “running” calculation of the scan time based upon the rising edge of the pulses commencing with the leader or header
15 information. The minimum and maximum scans times are calculated continuously in software with the interface 1608 during the scanning process to ensure a successful scan by the user.

Referring now to FIGURE 18, there is illustrated a sample message packet transmitted from the user’s PC 302 to the ARS 308. The message packet 1800
20 comprises a number of bits of information including the bar code information 1802 obtained from the user scanning the bar code 1606 with the input device 1600; the input device ID 1804 which is embedded in a memory in the input device 1600 and identifies it with a particular input device distributor; and a user ID 1806 which is derived from the software running on the PC 302 and which identifies uniquely with the user location. Note

that the message packet includes other necessary information for the proper transmission for point to point.

Referring now to FIGURE 19, there is illustrated a more detailed block diagram of the routing of the message packets in order to present the framed information to the user.

5 As is mentioned hereinabove, when the user scans a bar code 1606 using the input device 1600, a input device program running on the user PC 302 is operable to interpret the information output by the input device 1600 and generate a message packet for transmission over the GCN 306. The input device program assembles the message packet such that it is directed to the ARS 308 disposed on the GCN 306. The message packet
10 contains several pieces of information including the input device ID 1804 which links it to the input device distributor, the user ID 1806 which identifies the particular user using the input device 1600, and bar code information 1802 describing a particular product of interest to the user. This message from the PC 302 is transmitted over a path 1900 to the ARS 308 where the ARS database 310 is accessed to cross reference the ID information
15 1804 and bar code information 1802 to a particular advertiser and input device distributor. The ARS 308 returns a message packet over a path 1902 to the user PC 302 which contains routing information as to the location of various other sites disposed on the GCN 306, for example, the advertiser server 312 and input device distributor site 1616.

It can be appreciated that other information can also be provided by the ARS 308
20 which more closely targets the particular user of the input device 1600. For example, if it is known that a particular input device 1600 is sold in a certain geographic area, this information can be useful in targeting the particular user with certain advertising information relevant to that geographic area. In any case, the information returned from the ARS 308 over path 1902 provides enough information for the input device program running on the
25 user PC 302 to identify a number of other sites disposed on the GCN 306. The user PC 302 then processes the return message packet and routes another message packet over a

path 1904 to the advertiser server 312. The advertiser server 312 then returns product information of the particular product in which the user was interested back to the user PC 302 over a path 1906. Similarly, the user PC 302 routes information (e.g., the URL of the input device distributor site and the user profile) to the input device distributor site 1616 over a path 1908 in order to obtain information back over a path 1910 for framing any banners which identify the input device distributor. Additionally, the user PC 302 forwards a message packet to the E-commerce site 1618 over a path 1912 in order to return information regarding any particular advertisements the input device distributor wants to display to the user. The advertisements are returned to the PC 302 over a path 1914.

Referring now to FIGURE 20, there is illustrated a block diagram of a browser window according to the disclosed embodiment. The browser window 2000 is partitioned into a plurality of areas for framing specific information. A bar code area 2002 displays that product information in which the user was interested; an input device-specific area 2004 displays information about the input device distributor; and an E-commerce area 2006 displays advertising information that the input device distributor selects for display according to this particular user and input device 1600. As mentioned hereinabove, a program operable to process scanned bar code information with the unique input device 1600 develops the browser window by partitioning it into specific areas for the framing of information. Therefore, information returned from the E-commerce site 1608 is passed through the GCN 306 to the particular E-commerce frame 2006. Similarly, information about the particular product of interest is returned from the advertiser site 312 across the GCN 306 to the particular bar code specific area 2002. Information placed in the input device specific area 2004 is information about the input device distributor which is returned from the input device distributor site 1616 across GCN 306.

Referring now to FIGURE 21, there is illustrated a structure of information contained in the ARS database. The ARS database 310 contains a variety of information

required to properly interrogate and assemble packets for obtaining information from the various sites disposed on the GCN 306. The ARS database 310 has a database structure 2100 which contains addresses for the web sites containing the product information requested by the user when scanning the bar code 1606 with the input device 1600.

5 Under a PRODUCT heading 2102 are listed the particular bar codes and associated routing information for addressing the respective server location. For example, the ARS server 308 may contain any number of advertisers having unique URL addresses associated therewith. Therefore, the bar code 1606 of a particular product is associated with a unique URL address which routes any request for information of that product to that particular advertiser's site. Also part of the ARS database structure 2000 is a heading of
10 INPUT DEVICE under which is the input device ID 1804 and the distributor associated with that input device ID 1804.

It can be appreciated that there may be a number of distributors using the disclosed architecture such that each distributor has an ID embedded in the input device
15 1600 which uniquely identifies that input device with the particular distributor. Therefore, the unique input device ID 1804 needs to be listed with the respective distributors of that input device 1600 in order to process the information that needs to be framed and displayed to that particular user. Another heading under the ARS database structure 2100 is a user heading 2106 which contains profile information associated with that particular
20 user ID 1806. As mentioned hereinabove, the user ID 1806 is obtained via the input device software running on the PC 302 and upon installation or subsequent configuration may request that the user input certain profile information which may be used to target that particular user with products and services which identify with that user profile. The ARS database structure 2100 also contains an E-commerce heading 2108 which contains
25 information related to the bar code 1606 and an advertisement that may be triggered by the request for that information. For example, any bar code 1606 associated with a paper source 1602 can be associated with the specific information in the ARS database 310. A

user wishing to obtain information about a specific soft drink may, in fact, trigger an advertising response of a competitor product. Similarly, the user interested in information about that particular soft drink may also trigger information which is relevant to that particular product or a product which may normally be served in conjunction with that soft drink. Furthermore, if the user profile indicates that this individual has significant interest in finance or insurance, the request for information regarding this particular bar coded product may trigger advertisement from an E-commerce server 1618 related to information about finance and insurance. It should be noted that the information described as contained within the ARS database structure 2100 is not limited to what has been described, but may comprise any number of pieces of information used to present desired information to the computer display of the user.

Referring now to FIGURE 22, there is illustrated a flowchart of the process of receiving information from the user's perspective, and according to the disclosed embodiment. The input device software running on the user's PC 302 runs in the background until activated by output from the input device 1600. Therefore, flow moves to a decision block 2200 where if a scanned input does not occur, flow moves out the "N" path and loops back to the input of decision block 2200. On the other hand, if scanned input information is received, flow moves out the "Y" path to a function block 2202 where the input device software assembles a message packet containing the bar code information, the input device ID 1804 and the ARS 308 URL address. Additionally, the browser is launched in which this information is placed for transmission to the ARS 308. Flow then moves to a function block 2204 where the browser is partitioned into any number of areas in which information is displayed when obtained from the input device distributor site 1616, the E-commerce site 1618, and the advertiser server 312. It should be known that although three frames are shown in the particular window 2000 of this embodiment, the number of frames displayed in the window 2000 is limited only by the available real estate of the window 2000 area itself.

After the input device software partitions the browser window into one or more frames in preparation of receipt of return information, flow moves to a decision block 2206 where the computer waits for information to be returned from the various sites disposed on the GCN 306. If information is not returned, flow moves out the "N" path and simply
5 loops back to the input to continue monitoring for receipt of the information. If information has been received, flow moves out the "Y" path to a function block 2208 where routing information for each frame (or partitioned area of the window 2000) is inserted into one or more packets for transmission to the various sites. The various sites then return the requested information back to the PC 302, as indicated in function block 2210. Flow is
10 then to a function block 2212 where the proprietary software working in conjunction with the hosted browser places the returned information into the respective frames of the window. The user, viewing the display at PC 302, then perceives a variety of information, one of which is the particular product information which he or she requested, in addition to input device distributor information, and possibly other advertisements based upon the
15 user's profile.

Referring now to FIGURE 23, there is illustrated a flowchart of the process according to the ARS. The ARS 308 is operable to decode and process messages received from the GCN 306. Therefore, flow is to a decision block 2300 where, if bar code information is not received, flow is out the "N" path with loop-back to its input. If
20 bar code information has been received, flow is to a function block 2302 where a matching process occurs to link the bar-coded product information to its respective manufacturer. The ARS database 310 also associates the URL address of the manufacturer's server. When a match is found, the ARS 308 begins to assemble a message packet of information for transmission back to the PC 302, as indicated in function block 2304. The message
25 packet contains the product information and the URL address of the manufacturer's website. Flow then moves to a decision block 2306 where the input device ID 1804 is compared with the list of input device IDs issued by the particular input device distributor.

If the input device ID 1804 is validated, flow moves out the “Y” path to a function block 2308 where the message packet is appended with the input device ID 1804 and distributor routing address. Flow then moves to a decision block 2310 where the ARS 308 determines if any E-commerce information is to be associated with a particular input device ID 1804. If so, flow is out the “Y” path to a function block 2312 where the message packet is appended with the E-commerce routing string. The E-commerce routing string provides addressing for the E-commerce server 1618. Flow then moves to a function block 2314 where all message packets are returned back to the PC 302 for processing.

Referring back to decision block 2306, if the input device ID 1804 is determined to be invalid, flow moves out the “N” path and jumps forward to the input of decision block 2314, since the lack of a input device ID 1804 interrupts the link to any advertising provided by the E-commerce server 1618. At this point, the only information provided is the link to the advertiser server 312 for return of product information. Referring now to decision block 2310, if no E-commerce information is available, flow moves out the “N” path and jumps forward to the input of function block 2314 where the message packet back to the PC 302 contains only the URL of the advertiser server 312, the bar code information, the distributor server 1616 address and input device ID 1804 information.

Referring now to FIGURE 24, there is illustrated a flowchart of the process performed at the E-commerce site. The E-commerce server 1618 receives the message packet from the user PC 302, as indicated in function block 2400, and decodes the packet to perform a match with the bar coded information. Moving on to a decision block 2402, if the match is unsuccessful, flow is out the “N” path to a function block 2404 where the match is rejected. A message may be returned to indicate that a problem occurred and the user may need to re-scan the product bar code 1606. If a successful match occurs, flow moves out the “Y” path to a function block 2406 where the input device ID 1804 is matched with the bar code product information. The bar coded information may be

distributed to customers over a large geographic area. However, the input device 1606 may be coded for certain geographic areas. For example, a input device 1600 having an XXX ID may be restricted for sale in the Southwestern United States while a input device 1600 having a YYY ID may be sold only in the Northeast. In this way, geographic areas may be targeted with advertising more appealing to that particular area. Advertising returned to the user PC 302 may be focused further by obtaining a user profile when the software or input device 1600 are installed. In this way, advertising may be focused based upon the user profile. Therefore, flow moves to a function block 2408 to lookup the E-commerce action based upon the input device ID 1804 and the bar code information. Flow moves to a function block 2410 to assemble all the information into a packet for return to the user PC 302. The product information and/or user profile information may be returned. Flow is then to a function block 2412 where the message packet is transmitted.

Although it has heretofore been typical for users accessing computer networks such as the Internet to use personal computers (PCS) having a hard-wired network connection, an ever increasing number of users are connecting with various types of wireless devices. Such wireless devices include handheld computers (also known as personal digital assistants ("PDAs")) having integrated wireless Internet access, e.g., the Palm VIIx produced by Palm Inc., cellular telephones having integrated Internet access capabilities, e.g., telephones conforming to the Wireless Application Protocol (WAP) established by the Wireless Application Protocol Forum Ltd., two-way digital pagers and other commercially available devices. All of these wireless devices includes a processor and a transmitter/receiver for sending and receiving radio frequency (RF) signals to provide two-way digital communication between the device's processor and a computer network. Of course, numerous additional components, e.g., memories, displays and input devices, are present in these wireless devices, their specific nature depending upon the type of device and desired features. The general construction of such wireless devices is, however, conventional and thus will not be described in detail.

Referring now to FIGURE 25, there is illustrated a diagrammatic view of one embodiment of a system for connecting a wireless device to a remote location on a computer network. The system includes a beacon unit 2502 disposed at a geographic location 2504 and transmitting a beacon signal (denoted by arrow 2506) into a target region adjacent to the beacon location. The system also includes a beacon signal receiver circuit (hereafter "BSRC") 2508 disposed with a wireless device 2510 and operably connected to the processor of the wireless device. Upon receiving the beacon signal 2506, the BSRC 2508 sends control signals to the processor of the wireless device 2510. The processor of the wireless device 2510, in response to receiving these control signals, instructs the wireless device to connect to a specific remote location on a computer network. This connection can be completely automatic or it can be made at the option of the user, but in any case it obviates the need for the user to manually input a network address for the remote location.

In the embodiment illustrated, the beacon unit 2502 is mounted on an outdoor advertising structure (i.e., a billboard) 2522 located adjacent to a roadway 2514. The wireless device 2510 is disposed within an automobile 2512 traveling along the roadway 2514. As previously described, the wireless device 2510 includes a processor and a transmitter/receiver for sending and receiving RF signals (denoted by arrows 2516). The RF signals 2516 provide two-way digital communications with a computer network, in this case GCN 306, which may be the Internet. The RF signals 2516 allow communication between the processor of the wireless device 2510 and the computer network 306 through a wireless network interface 2518, which in this case also serves as an Internet service provider (ISP). For purposes of illustration, the network interface 2518 in FIGURE 25 shows only one antenna 2520; however, it will be appreciated that the typical wireless network interface comprises a plurality of antennas 2520 and associated radio equipment (not shown) which are distributed across the service area (e.g., in cells) and operably interconnected allowing the wireless device 2510 to maintain virtually unbroken

communications with the network 306 as it moves within the service area. It is noted that these wireless devices operate on a delay, such that a request for information may be buffered at the wireless device 2510 in the event of a communication interruption. When communications are resumed, then the request is sent. In the same way, reply information is buffered, such that there may be a delay in returning the information. This is easily facilitated at the ISP 2518, due to the nature of the packet nature of the information transferred. For example, a packet of request information may be buffered at the wireless device 2510 until communication is resumed, and then transmitted to the ISP 2518. Upon receipt, the ISP 2518 acknowledges to the wireless device 2510 that the information has been received. The ISP 2518 then handles the request outside of the wireless connection over link 2520. When connection is established with the advertiser server 312 and information retrieved, this information is buffered at the ISP 2518 and delivered to the wireless device 2510 when communications permit. Since the primary communication protocol is packet-based in nature, this type of buffering is easily facilitated.

Referring now to FIGURE 26, there is illustrated a diagrammatic view of the beacon unit 2502 of this embodiment. The beacon unit 2502 includes a transmitter 2602, a modulator 2604 operably connected to the transmitter, and a processor 2606 which is operably connected to the modulator. The transmitter 2602 transmits the beacon signal 2506 into the target region. The information content (i.e., modulation) of the beacon signal 2506 is supplied to the transmitter 2602 by the modulator unit 2604, which in turn receives the content from the processor 2606. The beacon signal 2506 may be modulated to carry information content in either digital or analog form. In the illustrated embodiment, the transmitter 2602 is a radio frequency (RF) unit for transmitting an RF beacon signal 2506. An antenna 2608 is operably connected to the transmitter 2602 to provide desired signal radiation strength and directional properties, thereby controlling the size and shape of the target region. Using an omnidirectional antenna 2608 will result in a generally circular target region which surrounds the location of the beacon unit 2502. Using a directional

antenna 2608 will result in a narrower, more focused target region, typically to one side of the beacon unit 2502. It will be appreciated that the frequency of the RF beacon signal 2506 will be different from the frequency used by the wireless device 2510 for network communication signals 2516, thereby allowing the signals to operate simultaneously without causing interference.

While the illustrated embodiment uses an RF transmitter 2602 for producing an RF beacon signal 2506, it will be readily apparent that other types of transmitters may be used in alternative embodiments to produce beacon signals having different characteristics. For example, the beacon unit may have an optical transmitter for transmitting an optical beacon signal. An optical beacon signal 2506 may have a carrier wavelength in the visible light portion, the infrared (IR) portion, or the ultraviolet (UV) portion of the electromagnetic spectrum. Such optical beacon signals may be produced using either non-coherent or coherent (e.g., laser) light sources. Optical beacon signals 2506 will typically require a line-of-sight path between the beacon 2502 and the BSRC 2508, however, this may be desirable for certain applications. Further, it avoids RF interference and licensing problems. In yet other embodiments, the beacon unit 2502 may have an acoustic transmitter for transmitting an acoustic beacon signal. The acoustic beacon signal 2506 may have a carrier wavelength in the human-perceptible frequency range or within the ultrasonic frequency range. Acoustic beacon signals 2506 will typically be of short range, but a line-of-sight path is not required.

In the embodiment shown in FIGURE 26, an electronic memory device 2610 is operably connected to the processor 2606. This could be conventional DRAM, flash DRAM or SRAM. Magnetic storage could also be utilized. The memory device 2610 includes one or more memory locations which store data, also known as "codes," that can be retrieved by the processor 2606. The processor 2606 sends signals indicative of the

retrieved codes to the modulator 2604 for incorporated as a component of the beacon signal 2506 transmitted by the transmitter 2602.

In the illustrated embodiment, two memory locations are provided in the memory device 2610, a first memory location 2612 and a second memory location 2614. Each memory location contains a different code. For example, the first code (denoted “MSG. CODE”) in the first memory location 2612 may be associated with a specific remote location on the network 306 to facilitate the connection of the wireless device receiving the code to that specific remote location. However, this association may have one of several forms. In one embodiment, the first code 2612 actually includes routing information (e.g., a URL or other network address) associated with a specific remote location on the network. In other words, the routing information is actually “embedded” or “encoded” in the first code 2612. In an alternative embodiment, the first code 2612 does not actually include routing information to the remote location, but rather is associated with the remote location by other means. This may be by association of the first code 2612 and the remote location in a secondary database such as the advertiser server 312 as further described below.

The second code (denoted in this example by “LOC. ID”) in the second memory location 2614 is also transmitted by the transmitter 2602 as a component of the beacon signal 2506. The second code may be associated with an attribute of the beacon unit 2502. Examples of such attributes are the geographic location (i.e., LOC ID) of the beacon unit, a serial number of the beacon unit and/or a type descriptor characterizing the type of beacon unit. Each of these attributes can be used to facilitate the connection of the wireless device 2510 receiving the code to the most appropriate specific remote location on the network 306. In some embodiments, the selection of remote location for connection of the wireless device 2510 may be made by considering both the first code 2612 and the second code 2614. Thus, for example, if the first code “MSG CODE” was

associated with a particular restaurant chain (e.g., "Burger X"), and the second code "LOC. ID" was associated with the geographic location of the beacon unit, then the invention could be used to connect the wireless device 2510 to a remote location on the network 306 having information as to the geographic location of the nearest Burger X restaurant (relative to the beacon unit location). Alternately, where the selection of remote location is controlled only by the first code, then the second code can be used to collect information regarding the source of the connection, e.g., to determine the "ratings" (i.e., advertising effectiveness) of a particular beacon unit 2502.

It will be apparent that the association between the second code and the beacon unit attribute may have one of several forms, similar to those previously described for the first code. Thus, the second code may actually include the attribute, e.g., location, serial number or type descriptor, of the beacon unit embedded therewithin. Alternatively, the second code may be associated with the beacon unit attribute in a secondary database such as the ARS 308. Further, it will be apparent that some embodiments may include only one code, in which case the first code may be associated with any of the beacon unit attributes (e.g., location, serial number or type descriptor) as previously discussed.

An input/output ("I/O") interface circuit 2616 may be included in the beacon unit 2502 to allow the memory unit 2610 to be reprogrammed with new codes. The I/O circuit 2616 is operably connected between the processor 2606 and an external instruction source 2618. The I/O circuit 2616 is thus operably connected to the memory unit 2610. Specifically, the I/O circuit 2616 receives instruction signals (denoted by reference number 2620) from the external instruction source 2618 and transforms them into system instruction signals (denoted by reference number 2622) usable by the processor 2606. In response to receipt of the system instruction signals 2622, the processor 2606 accesses the memory unit 2610 and changes the codes in memory locations, e.g., locations 2612 and 2614. In this way, the beacon unit 2502 can be updated to change the remote

location to which it directs nearby wireless devices. It will be apparent that a variety of external instruction sources may be utilized. In the illustrated embodiment, the instruction source 2618 is a public switched telephone network ("PSTN") connected to the beacon unit 2502 by telephone lines 2524 (see FIG. 25). In such a case, the I/O circuit 2616 will include a telephone modem circuit allowing the beacon unit 2502 to be updated from a remote location. In another embodiment, the instruction source 2618 may be a keypad or keyboard attached directly to the I/O circuit 2616. In this case, no telephone lines are required, however, service personnel would need to visit the beacon unit 2502 to update the programming. In yet another embodiment, the instruction source 2618 may be an RF receiver circuit, an optical receiver circuit, or an acoustic receiver circuit. In such cases, the beacon unit 2502 may be updated by transmitting instructions on RF, optical or acoustic signals having a frequency appropriate for the respective receiver circuit.

Referring now to FIGURE 27, there is illustrated a diagrammatic view of the beacon signal receiver circuit (i.e., "BSRC") 2508 of this embodiment and the associated wireless device 2510. As previously described, the BSRC 2508 is disposed with the wireless device 2510. In the illustrated embodiment, the BSRC 2508 has the form of an add-on module which is attached to the exterior shell 2702 of the wireless device 2510. The two devices pass electronic signals through an electrical interface comprising cooperating electrical connectors 2704 and 2706 located on the BSRC 2508 and wireless device 2510, respectively. In alternative embodiments, however, the BSRC 2508 may be supplied as an integral part of the wireless device 2510, and located entirely within its exterior shell 2702. In such case, the interface between the BSRC 2508 and the wireless device 2510 would be an integral part of the overall device, and the discrete connectors 2704 and 2706 would be unnecessary.

The BSRC 2508 includes a receiver unit 2708 and a processor 2710. The receiver unit 2708 is adapted to receive the beacon signal 2506 transmitted by the beacon

unit 2502. In the illustrated embodiment, the receiver unit 2708 is an RF receiver adapted to receive signals from the RF transmitter 2602, and thus is provided with an antenna 2712 to improve reception. In other embodiments, however, the receiver unit 2708 may be an optical receiver or an acoustic receiver to correspond to the type of transmitter used by the beacon unit 2502. In still other embodiments, the BSRC 2508 may include multiple receiver units of different types (e.g., an RF unit and an optical unit) or operating at different wavelengths. The beacon signal 2506 received by the receiver unit 2708 is then demodulated as necessary to extract the information content, e.g., the codes transmitted from the beacon unit memories 2612 and/or 2614. Signals indicative of the received codes (or other information content) are then passed to the BSRC processor 2710. In response to receiving the signals indicative of the received codes, the BSRC processor 2710 sends control signals across the interface 2704, 2706 to the processor 2714 of the wireless device 2510.

As previously discussed, the wireless device 2510 includes a processor 2714 operably connected to an RF transmitter/receiver unit 2716. The RF transmitter/receiver unit 2716 transmits and receives RF signals 2516 to provide two-way communication between the wireless device 2510 and the computer network 306. The wireless device 2510 may further include various types of a memory unit 2718, a keypad, keyboard, touch pad or other user input device 2720, a display screen 2722, and an audio input/output device 2724 (e.g., speaker and/or microphone), depending on its exact type, i.e., whether it is a Internet-ready telephone, an Internet connected personal digital assistant or some other type of network wireless device. The control signals received by the wireless device processor 2714 from the BSRC processor 2710 cause the wireless device 2510 to send RF signals 2516 to the computer network 306 whereby the wireless device is connected to a specific remote location on the network. These RF signals 2516 may include components indicative of the codes received from the memory 2610 of the beacon unit 2502.

In the embodiment shown in FIGURE 27, an electronic memory device 2726 is operably connected to the BSRC processor 2710. The memory device 2626 includes one or more memory locations which store data, i.e., "codes", that can be retrieved by the BSRC processor 2710. The BSRC processor 2710 can send signals indicative of the retrieved code to the wireless device processor 2714, which in turn may incorporate the code as a component of the RF signal 2516 used to connect the wireless device 2510 to the remote site on the computer network 306. Thus, the RF signals 2516 transmitted by the wireless device 2510 may include components indicative of codes, or portions thereof, received from the memory 2610 of the beacon unit 2502 and/or components indicative of codes received from the memory 2726 of the BSRC 2508.

In the illustrated embodiment, one memory location 2728 is provided in the memory device 2726 (denoted "SER. NO."). In this embodiment, the code is associated with a serial number for the individual BSRC 2508. This is typically non-volatile memory. This serial number can be provided to the remote location to which the wireless device 2510 is connected to allow tracking of inquiries or the collection of data regarding the effectiveness of the system. In another embodiment, the code may be associated with a type descriptor characterizing the type of BSRC 2508. This type descriptor, when transmitted to the advertiser server 312, may allow selection of a remote location on the network having content which is optimized for display on the particular type of BSRC being connected. In other embodiments, the code located in the memory location 2728 may be associated with the address of a remote location on the network 306, for example the location of the advertiser server 312.

Once the wireless device 2510 has received the codes from the beacon unit 2502 and the BSRC 2508, the connection of the wireless device to a remote location on the computer network 306 may be accomplished generally as described for previous embodiments receiving codes from external devices, e.g., from bar code readers, audio

tones embedded in broadcasts or recorded media. For example, as illustrated in FIGURE 25, a first computer, e.g., the ARS 308, is disposed on the computer network 306. A computer database, e.g., the advertiser database 310, is operably connected to the first computer 308. The computer database 310 includes a plurality of routing information for remote locations on the computer network and a plurality of first codes (i.e., corresponding to the codes from the beacon unit memory 2612) and associating each of the routing information with at least one of the first codes. Upon receiving a message packet (i.e., a signal containing information components which are indicative of the first code) transmitted from the wireless device 2510 across the network 306, the first computer 308 accesses the computer database 310, retrieves the routing information associated with the particular first code, and transmits the routing information associated with the particular first code across the computer network back to the wireless device. It will be readily apparent that, in some embodiments the routing information in the database 310 may be further associated with a plurality of additional codes (e.g., second code from beacon unit memory 2614 and third code from BSRC memory 2728) to allow for further refining of the selection of routing information to be transmitted back to the wireless device 2510.

In response to receiving the routing information associated with the particular first code (and any additional codes, if applicable, as described above) from the first computer 308, the wireless device 2510 then sends a second message packet across the network to a remote location as directed by the routing information just received. This may be the desired remote location, or alternatively, codes incorporated into the second message packet may be evaluated to select a particular remote location from among a plurality of locations accessible through this site. Once the determination has been made, the wireless device 2510 is connected to the desired remote site on the network 306. In most cases, information content will be returned from the remote site to the wireless device for further evaluation or display to the user.

Referring now to FIGURES 28a-28d, there is illustrated a flowchart of the process for connecting a wireless device to a remote location on a computer network in accordance with another aspect of the invention. The process begins in the "START" block 2802 (FIGURE 28a) and then proceeds to function block 2804, wherein the

5 beacon unit processor 2606 retrieves the code or codes from the beacon unit memory 2610. In the illustrated embodiment, a first and second code are retrieved from the beacon unit memory. The process then proceeds to function block 2806, wherein the beacon unit 2502 transmits as a continual and/or repetitive broadcast into the target zone the beacon signal 2506 which incorporates information indicative of the first code and the

10 second code. The process then proceeds to function block 2808, wherein the BSRC 2508 which is within the target zone receives the beacon signal 2506 and extracts the first and second codes. If the BSRC 2508 includes a memory unit 2726 (this test being represented by the decision block 2809), the process then proceeds to function block 2810 where the BSRC processor 2710 retrieves the code or codes from the BSRC

15 memory. If the BSRC 2508 does not include a memory unit, then function block 2810 is omitted. The process then proceeds to function block 2812 (FIGURE 28b), wherein the BSRC processor 2710 passes the first, second, and/or third codes (as applicable) to the processor 2714 of the wireless device 2510 for buffering therein.

Once the wireless device 2510 receives the signals indicative of codes from the

20 BSRC 2508, the process then proceeds to function block 2814, wherein the wireless device sends RF signals 2516 having a first message packet which incorporates the codes via the ISP 2518 to a first location on the network 306. In some embodiments, e.g., where the codes from the beacon unit 2502 actually include embedded routing information to the desired remote location, e.g., location 2526 (FIGURE 25), the first message packet

25 may be routed directly to the desired remote location on the network 306 using the routing information from the code. In the illustrated embodiment, however, the codes in the RF signals 2516 do not contain embedded routing information relating to the desired remote

location. Therefore, it is necessary for the first message packet to be routed to a known intermediate site, e.g., ARS 308, where the codes can be used to retrieve the necessary routing information from a database, e.g., database 310. In such case, the RF signals 2516 will incorporate default routing information necessary to guide the first message packet to the intermediate location. It will be understood however, that this fixed routing information, i.e., to an intermediate location used to obtain further routing information to remote sites, is to be distinguished from the routing information to the desired remote location. The process next proceeds to function block 2816, wherein the intermediate server 308 receives the message packet including the codes received from the beacon unit 2502 and/or BSRC 2508 and extracts the codes. The process then proceeds to function block 2818, wherein the intermediate server 308 accesses the computer database 310 and retrieves the routing information associated with the codes.

After retrieving the routing information associated with the codes received from the beacon unit 2502 and/or BSRC 2508 from the computer database 310, the process continues to function block 2820, wherein the intermediate server 308 sends another message packet including the routing information back across the network 306 to the wireless device 2510. The process then proceeds to function block 2822 (FIGURE 28c), wherein the wireless device 2510 sends a second message packet across the network 308 to a remote location using the routing information just retrieved from the intermediate site 308. The second message packet may also include some or all of the codes received from the beacon unit 2502 and/or BSRC 2508. The process then proceeds to function block 2824, wherein the second message packet is received at the remote location specified by the routing information retrieved from the intermediate site 308. As represented by the decision block 2826, in some embodiments, this remote location may be the desired remote location 2526, in which case the process proceeds to function block 2828 and the connection of the wireless device 2510 to a remote location on the network has been completed (as denoted in function block 2830). In the illustrated embodiment, however,

this location is a “portal” site, e.g., advertiser server 312, providing access to a plurality of additional remote locations on the network, e.g., content locations designated by reference numbers 2526 and 2528. In this latter case, the process proceeds from decision block 2826 to function block 2832. In the function block 2832, the codes in the second message packet (which originated from the beacon unit 2502 and/or BSRC 2508) are used to access a database or lookup table at the portal location 312 associating each of the plurality of remote locations with one or more of the codes. This process then also proceeds to function block 2830, wherein the associated one of the plurality of remote locations, i.e., the desired location 2526, is connected to the wireless device to complete the basic process.

In the illustrated embodiment, the process is extended beyond the basic process to an additional function block 2832, wherein information content from the remote site 2526 is sent back across the network 306 to the wireless device 2510. The extended process next proceeds to function block 2834, wherein content from the desired remote location is received by the wireless device 2510. The extended process then proceeds to function block 2836, wherein the received content is further processed or displayed by the wireless device 2510 to the user. The extended process then proceeds to the “END” block 2832 indicating that the extended process is complete.

Referring now to FIGURE 29, there is illustrated an aerial view (i.e., plan view) of a geographic region 2900 in which an embodiment of the system has been deployed. The geographic region 2900 includes a first roadway 2514, a second roadway 2902, an intersection 2904 between the two, and a retail establishment 2906 disposed alongside the second roadway. In this embodiment, three beacon units denoted by reference numerals 2502a, 2502b and 2502c, respectively, are positioned along the first roadway 2514. The beacon units may be mounted on antenna towers, billboards, buildings or even smaller structures such as park benches, depending upon the type of beacon and coverage range

required. In this example, each of the beacon units 2502a, 2502b and 2502c transmits an RF beacon signal 2506 using an omnidirectional antenna 2604, resulting in circular target regions 2910a, 2910b and 2910c, respectively. In this embodiment, the beacon units 2502a, 2502b and 2502c are spaced apart a distance D1 which is greater than the sum of the radii for adjacent target regions, thus, the target regions 2910a, 2910b and 2910c form “cells” which do not overlap. This arrangement allows adjacent beacon units to broadcast beacon signals on the same frequency without interfering with one another, and it also allows the BSRC 2508 to utilize a single reception frequency. It will be apparent, however, that other embodiments of the invention may employ beacon units transmitting on different and/or multiple frequencies and beacon signal receiver units receiving on different and/or multiple frequencies.

Referring still to FIGURE 29, as the automobile 2512 travels along the first roadway 2514 in the direction indicated by arrow 2912, it passes sequentially through the target regions 2910a and 2910b (as indicated by phantom lines) to its current position in target region 2910c. A BSRC 2508 operably connected to a wireless device 2510 in the automobile 2512 will therefore sequentially receive beacon signals from each of the beacon units 2502a, 2502b and 2502c. As previously described, the wireless device 2510 may be connected to a remote site on the network upon receiving each of the beacon signals. For example, the first beacon unit 2502a may cause the wireless device 2510 to connect to a remote location providing geographically relevant information regarding the nearby retail establishment 2906 and indicating that it can be reached by turning at an upcoming intersection. The third beacon unit 2502c, whose target area 2910c covers the intersection 2904, may cause the wireless device 2510 to connect to a remote location also providing geographically relevant information, i.e., that the driver should turn onto roadway 2902 at the current intersection (i.e., intersection 2904) to reach establishment 2906. On the other hand, the second beacon unit 2502b, may cause the wireless device 2510 to connect to a

remote location which provides information having no geographical relevance, e.g., information relating to the product advertised on an adjacent billboard.

It will be appreciated that, while all the previously described embodiments utilize a beacon unit 2502 having a fixed geographic location, this is not a requirement of the invention. In other embodiments, the beacon unit 2502 may be mounted on a vehicle, e.g., a bus, a taxi, a truck, a train, an automobile, or even an aircraft, and equipped with a mobile power supply so that it may transmit the beacon signal 2506 as the vehicle moves. The target area of the beacon signal transmission thus moves as the vehicle moves, encompassing various wireless devices whether they are moving or stationary. Those wireless devices equipped with a compatible BSRC 2508 may then be automatically connected to a remote location on a network as previously described.

Although the preferred embodiment has been described in detail, it should be understood that various changes, substitutions and alterations can be made therein without departing from the spirit and scope of the invention as defined by the appended claims.
